Conflict Escalation Dashboard Report

Automated portfolio risk monitor | Generated 2026-03-12 00:51 UTC

This report summarizes the model's current read on conflict escalation risk, probabilistic conflict duration, and the associated portfolio regime. The framework blends market-derived signals, RSS/GDELT news proxies, optional event data, and ML-aided escalation probabilities.

Metric	Latest
Escalation Score	0.162
Model Confidence	93.0%
P(De-escalation)	0.0%
P(Stabilization)	37.8%
P(Escalation)	62.2%
P(Short War 2-4w)	28.6%
P(Extended 1-3m)	39.8%
P(Long Proxy 6-24m)	31.6%
Portfolio Regime	Stabilization
Recommended Action	Stay balanced, avoid headline chasing, keep hedges lighter but intact, favor quality and liquidity while waiting for cleaner confirmation.

Interpretation

The model currently indicates a **Stabilization** regime with **93.0%** confidence based on live data coverage. Near-term conflict duration probabilities are tilted toward **39.8%** for an extended 1-3 month conflict.

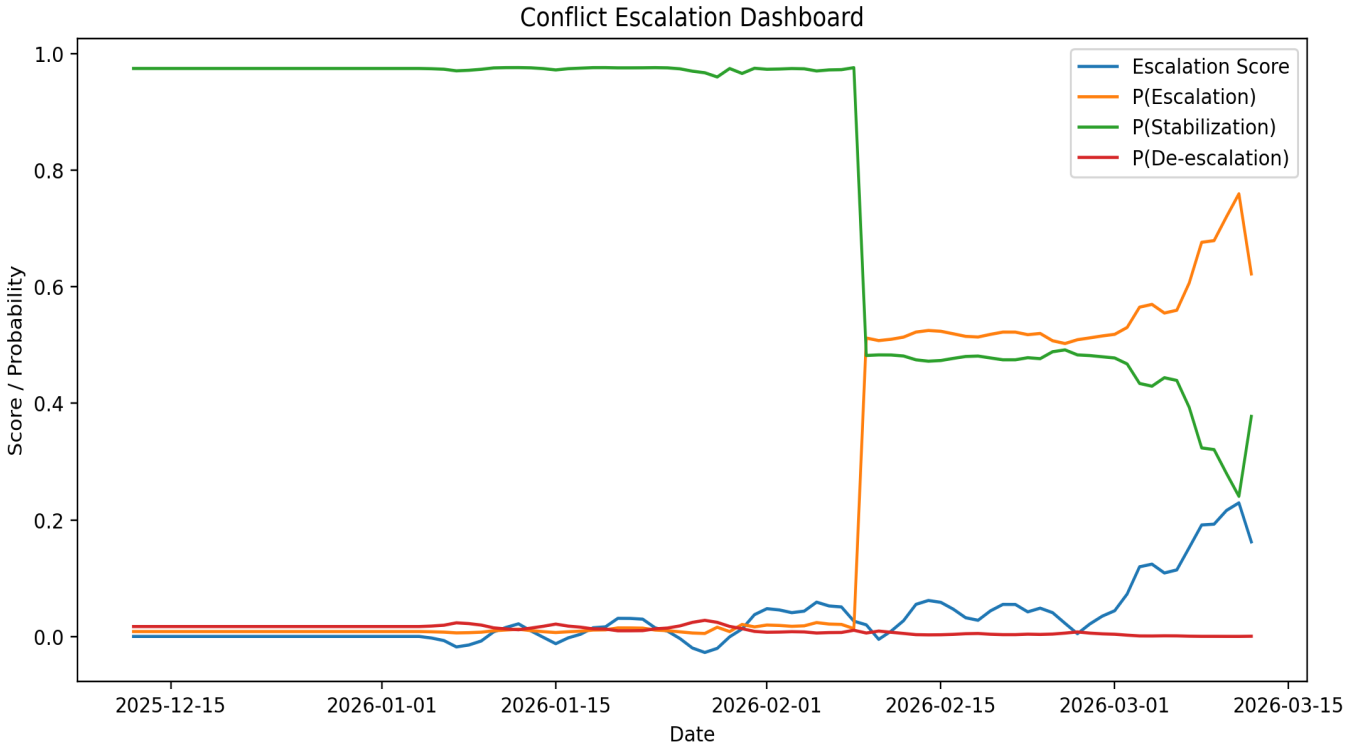
Data availability

Layer	Status
Market layer	Live
News volume/tone	Live
Event layer	Down

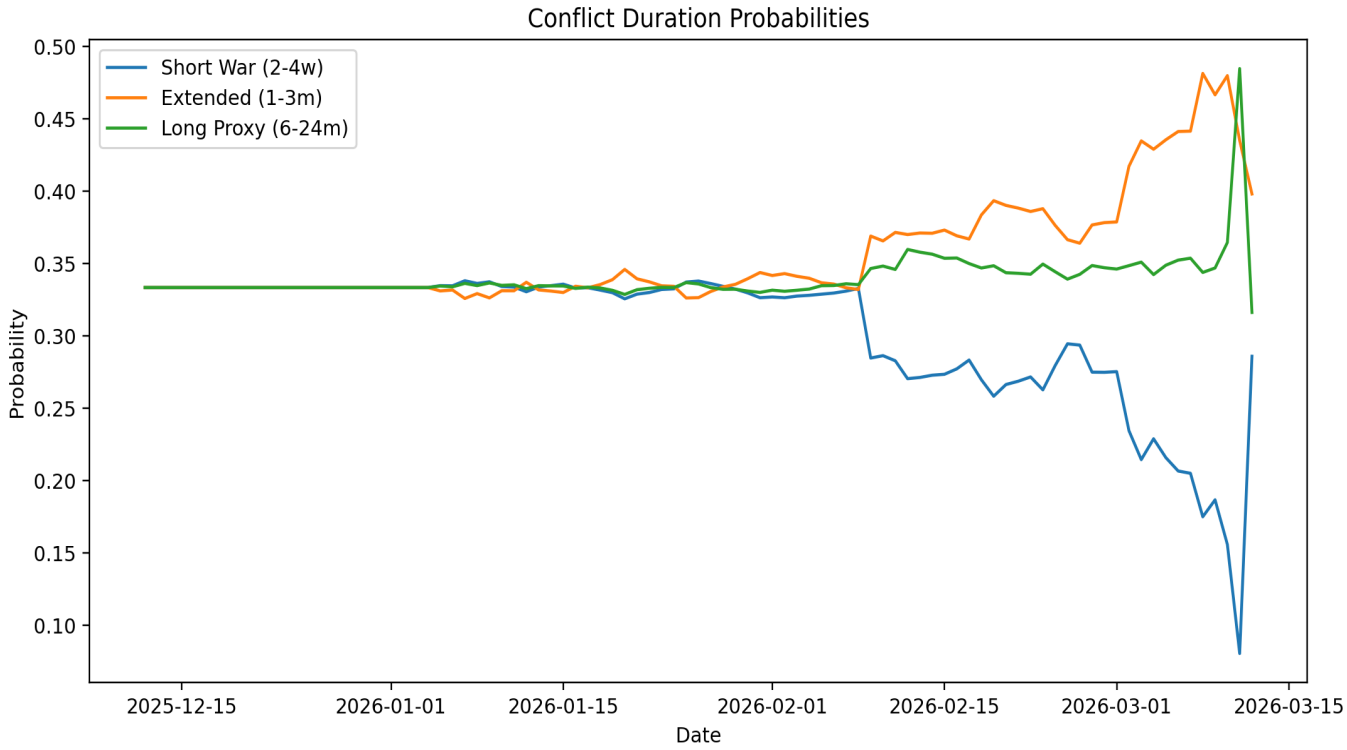
Method / caveat notes

Missing signals no longer dilute the model. The escalation score is availability-adjusted so only live signal families contribute to the normalized score. If GDELT is rate-limited, the notebook attempts to backfill with RSS-derived keyword signals; if ACLED is unavailable, the event layer remains neutral.

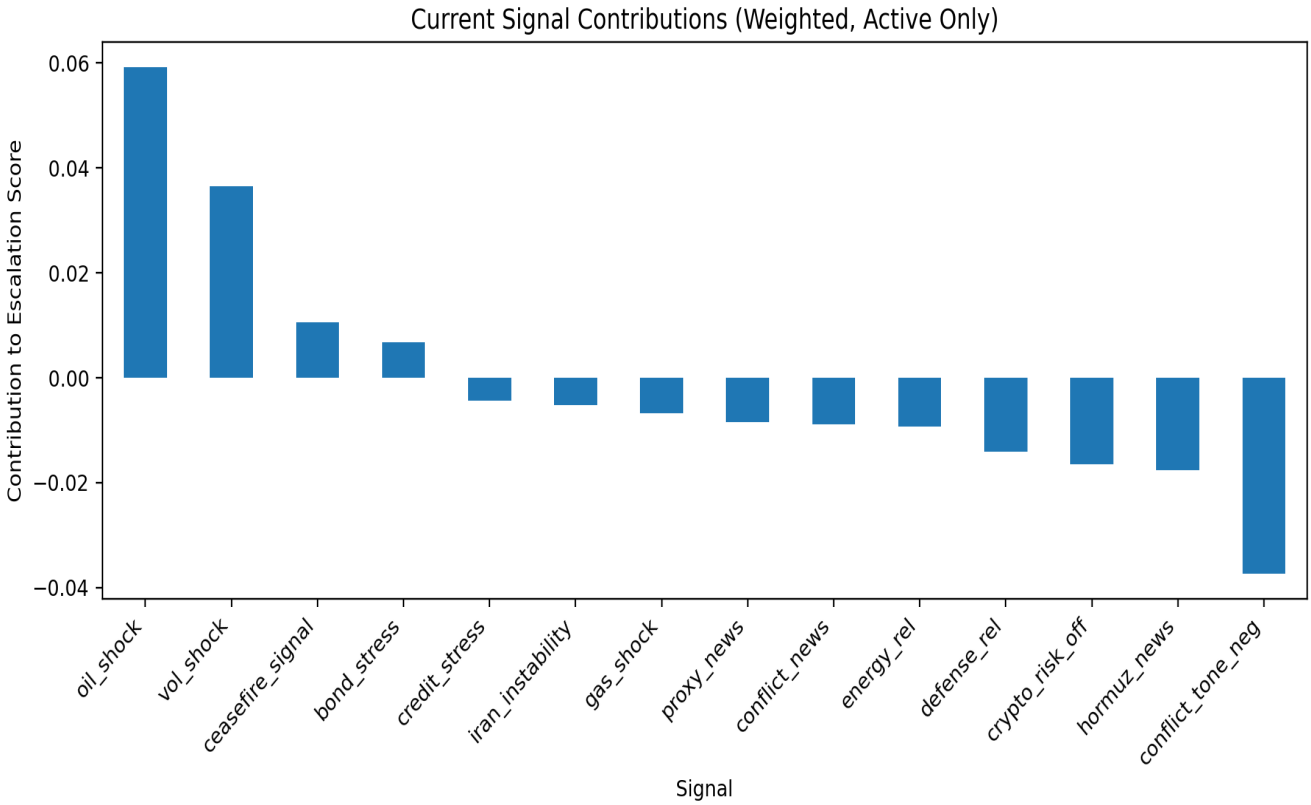
Conflict Escalation Trend



Conflict Duration Probabilities



Signal Contributions



Inactive / unavailable signals
